The Clinical Case for Smoking Cessation for RESPIRATORY PATIENTS

**What is this initiative aiming to achieve?**

The aim of this initiative is to provide clinical support for temporary abstinence with a view to prompting a permanent quit supported by a referral to local NHS Stop Smoking Services. To gain maximum benefit, hospital associated abstinence needs to lead to permanent quitting. However, temporary abstinence during treatment and recovery may still have worthwhile benefits.

**What is the relationship between smoking and respiratory illnesses?**

Cigarette smoke has been identified as a risk factor for the development, aggravation and/or progression of a number of respiratory diseases including COPD, lung cancer, asthma and interstitial lung diseases (respiratory bronchiolitis-associated interstitial lung disease, desquamative interstitial pneumonia, pulmonary Langerhans cell histiocytosis). People who smoke are also at an increase risk of serious respiratory infections such as pneumococcal pneumonia, influenza and tuberculosis.

**What are the health benefits of quitting for respiratory patients?**

Successful quitting will not only benefit a patient’s long term health by reducing the risk of developing other diseases, smoking abstinence may help a patient recover quicker by eliminating the acute effects of smoking on the body and smoking cessation has been associated with benefits in terms of respiratory disease outcomes (see below).

**Main acute effects of smoking on the body (estimated time of recovery after cessation, if known)**

- Increase in sympathetic tone leading to an increase in blood pressure, heart rate and vasoconstriction which increases demand for oxygen and cardiac function. (24-48 hrs)
- Formation of carboxyhaemoglobin and decreased oxygen dissociation rate in the blood leading to reduction in oxygen delivery to the tissues. (8-24 hrs)
- Formation of carboxymyoglobin leading to reduction in oxygen storage in the muscles. (8-24 hrs)
- Increase in red blood cell production which leads to increase in blood viscosity, a decrease in tissue perfusion, a decrease in oxygen delivery to the tissues and potentiation of thrombotic process. (11-12)
- Hypersecretion of mucus, narrowing of the small airways, decrease in ciliary function and change in mucus rheology leading to a decrease in mucociliary transport. (12-72 hours)
- Changes in functioning of a range of immune cells (pro- and anti-inflammatory cytokines, white blood cells, immunoglobulins) which lead to decreased immunity and are associated with atherosclerosis (1 week-2 months)
- Induction of hepatic enzymes which increases drug metabolism through both pharmacokinetic and pharmacodynamic mechanisms (6-8 weeks)

**Why intervene in secondary care?**

Hospitalisation is an opportune time to encourage patients to stop smoking for four main reasons.

- Firstly, this time is often a “teachable moment” where patients are more receptive to intervention and are more motivated to quit.
- Secondly, the hospital's no smoking environment creates an external force to support abstinence.
- Thirdly, patients are ideally placed to be given information about treatment options, support through withdrawal and signposted to specialist services.
- Fourthly, abstaining from smoking at this time can lead to significant health benefits.
Effect of smoking and smoking cessation in respiratory illness

Asthma
- Smoking is associated with more severe symptoms, an accelerated decline in lung function, increased hospital-based care and increased mortality following hospital admission with an acute episode of near fatal exacerbation, compared to levels seen in non-smoking asthma patients. 14
- Smoking has been associated with corticosteroid-resistance and poorer symptom control compared with non-smoking asthma patients. 15;16
- Smoking cessation has been shown to improve lung function, reduce self-reported symptoms, medication use and improve asthma specific quality of life scores. 17-19

COPD
- Smoking cessation is the most effective method of slowing respiratory function decline associated with COPD.1;20-22
- Smoking cessation has been associated with a decrease risk in COPD exacerbations, with the size of the risk reduction increasing with duration of smoking abstinence. 23
- Smoking cessation is associated with a 43% decreased risk of hospitalisation (HR 0.57 (95% CI 0.33-0.99). 24

Respiratory infections
- Smoking has been associated with an increase risk of contraction, activation, relapse and mortality due to TB. 25-27
- Smoking cessation reduces the risk of developing bronchitis and pneumonia compared to continued smoking. 6

How was this information sheet put together?

This information is a summary of the current scientific evidence on the association between cigarette smoking and respiratory diseases. Studies were found by searching MEDLINE and EMBASE using combined exploded subject headings of “pneumonia, bacterial, “respiratory tract infections” “respiratory tract diseases” and “tobacco use cessation” from 01/1990 – 10/2009 and by searching the Report of the US surgeon general on the health benefits of smoking cessation. Evidence has been included in this summary from cohort studies, randomised controlled trials and reviews only.
